

## 2.1.3 SEARCHING AND SORTING ALGORITHMS

## Standard searching algorithms:

<ul> <li>Binary search</li> <li>Linear search</li> <li>A BINARY SEARCH requires data to be sorted in order before it can be searched. A LINEAR SEARCH does not –the algorithm will look at every item in list until it either locates the data or reaches the end of the list. The binary search is the more efficient of the two</li> </ul>	<pre>INPUT item to be searched for found = False numbers = [4,2,6,1,5,3] REPEAT Compare item with current item in list IF current item is the item searched for then found = True UNTIL end of list OR found = True IF found = True PRINT ("Item found") ELSE PRINT ("Item not found")</pre>
We are searching for 6 in a sorted list1234567List is split in two at the mid point12345676 > 4 so discard items less than 4BINARY SEARCHList is split in two at the mid point45676 > 5 so discard items less than 5List is split in two at the mid point45676 > 5 so discard items less than 5List is split in two at the mid point67Item has been found	
Standard sorting algorithms: <ul> <li>Bubble sort</li> <li>Merge sort</li> <li>Insertion sort</li> </ul>	You need to be familiar with searching sorting algorithms but there is no need for you to be able to code them
<ul> <li>-A BUBBLE SORT is an algorithm for sortin</li> <li>-The algorithm works by going through a lis unordered data and evaluating the data in p</li> <li>-If two data items are in the wrong order the exchanged.</li> <li>-The algorithm then moves to the next pair.</li> <li>-When the algorithm reaches the end of the process will be repeated until all data has b correctly. This might take SEVERAL PASS the data.</li> </ul>	Ing data.       STARTING DATA       4       2       6       1       5       3         t of pairs.       Items 1 & 2       2       4       6       1       5       3       2>4 so SWAP         eavare       Items 2 & 3       2       4       6       1       5       3       2>4 so SWAP         eavare       Items 2 & 3       2       4       6       1       5       3       4<6 NO SWAP
-A MERGE SORT is a DIVIDE AND CONQUER algorithm; -First of all, the items of data in a list are divided in half until each item is in a SUBLIST of one item.(This is the DIVIDE stage) -The algorithm will then merge each sublist, after comparing and sorting them as appropriate. -When all of the data has been merged back into a single list it will be in the correct order. (This is the CONQUER stage) - Merge sorts are more efficient than bubble or insertion sorts. -A MERGE SORT is a DIVIDE and the state of the stat	
<ul> <li>-An INSERTION SORT is more efficient than a bubble sort.</li> <li>-The insertion sort works in a similar way to sorting a hand of cards.</li> <li>-The algorithm works by comparing the current data item with the other items in the list</li> <li>- If the data item is in the wrong place, it is shifted to left until it is in the correct place.</li> <li>- This continues until all the</li> </ul>	Unsorted list $\begin{array}{c cccc} 4 & 2 & 6 & 1 & 5 & 3 \\ \hline & & & & \\ & & & & \\ & & & & \\ & & & & $
items of data are in the correct place. 6 would	be inserted (6 is already in the correct place) <b>1 2 3 4 5 6</b>
